Meropenem
Newborn use only

2020

<table>
<tr><td>Alert</td><td>The Antimicrobial Stewardship Team recommends this drug is listed under the following category: Restricted.
Widespread use of carbapenems has been linked with increasing prevalence of infections caused by methicillin-resistant Staphylococcus aureus (MRSA), vancomycin-resistant enterococci (VRE), multi-resistant Gram-negative organisms and Clostridium difficile.</td></tr>
<tr><td>Indication</td><td>Severe infections (e.g., sepsis or meningitis) caused by Gram-negative organisms resistant to other conventional antibiotics but susceptible to meropenem e.g., Extended Spectrum Beta Lactamase (ESBL)-producing organisms.
Note: Meropenem is NOT active against many resistant Gram-positive organisms, such as MRSA and most Staphylococcus epidermidis. Vancomycin is first-line therapy for these. Meropenem does have activity against penicillin-susceptible Gram-positive organisms and most anaerobic organisms. For individual advice, discuss therapy with a microbiologist or infectious diseases physician.</td></tr>
<tr><td>Action</td><td>Meropenem is a carbapenem. It inhibits cell wall synthesis. (1)

Meropenem is a better choice than imipenem for central nervous system infections. Meropenem attains a higher concentration in the cerebrospinal fluid particularly with inflamed meninges and has a lower incidence of seizures than imipenem.</td></tr>
<tr><td>Drug type</td><td>Carbapenem antibiotic.</td></tr>
<tr><td>Trade name</td><td>Meropenem APOTEX, Meropenem DBL, Meropenem GH, Meropenem Juno, Meropenem Kabi, Meropenem Sandoz, Merrem</td></tr>
<tr><td>Presentation</td><td>500 mg vial
1000 mg vial</td></tr>
<tr><td>Dose</td><td>Non-CNS and Non-Pseudomonas Sepsis
<table>
<tr><th>Gestational Age at birth</th><th>Postnatal Age</th><th>Dose</th><th>Interval</th></tr>

<tr><td>Any</td><td>Any</td><td>40 mg/kg</td><td>8 hourly</td></tr>
</table></td></tr>
<tr><td>Dose adjustment</td><td>Assess for renal impairment prior to using higher doses as meropenem is primarily excreted via kidneys.</td></tr>
<tr><td>Maximum dose</td><td></td></tr>
<tr><td>Total cumulative dose</td><td></td></tr>
<tr><td>Route</td><td>IV infusion.</td></tr>
<tr><td>Preparation</td><td><u>Infants ≤1kg</u>
Add 9.6 mL of water for injection to 500 mg vial to make a 50 mg/mL solution OR
Add 19.1 mL of water for injection to 1g vial to make a 50 mg/mL solution.

FURTHER DILUTE
Draw up 2 mL (100 mg of meropenem) of the above solution and add 8 mL sodium chloride 0.9% to make a final volume of 10 mL with a final concentration of 10 mg/mL.

<u>Infants >1kg or fluid restricted</u>.
Add 9.6 mL of water for injection to 500 mg vial to make a 50 mg/mL solution.
FURTHER DILUTE
Draw up 4 mL (200 mg of meropenem) of the above solution and add 6 mL sodium chloride 0.9% to make a final volume of 10 mL with a concentration of 20 mg/mL.</td></tr>
<tr><td>Administration</td><td>IV infusion over 4 hours. (5)
May be given over 15 to 30 minutes if longer infusion time is not feasible.</td></tr>
<tr><td>Monitoring</td><td>Renal function.
Liver function.
Electrolytes</td></tr>
</table>

Contraindications	Hypersensitivity to penicillins, cephalosporins and carbapenems.
Precautions	Colitis−due to risk of pseudomembranous colitis. Renal impairment.
Drug interactions	Sodium valproate− meropenem may result in clinically significant reduction in concentration of sodium valproate, which may cause seizures.
Adverse reactions	Phlebitis, diarrhoea (up to 6% in children), anaemia and eosinophilia.
Compatibility	Fluids: sodium chloride 0.9% (preferred for stability), glucose 5%, glucose 10%, Y-site: Amino acid solutions, anidulafungin, caspofungin, linezolid, atropine, dexamethasone sodium, gentamicin, heparin sodium, metronidazole.
Incompatibility	Fluids: Mannitol 10% Y-site: Dolasetron, ketamine, zidovudine.
Stability	Use immediately after preparation. Diluted solutions are potentially unstable, particularly glucose containing solutions and should be discarded if not used immediately.
Storage	Vial: Store at room temperature.
Excipients	Sodium carbonate
Special comments	Meropenem 1 g vial contains 3.92 mmol of sodium.
Evidence	**Efficacy:** Carbapenems may be considered the treatment of choice for empirical treatment of patients with ESBL-producing *Enterobacteriaceae* bacteraemia. A systematic review of carbapenems for the treatment of patients with extended-spectrum β-lactamase (ESBL)-positive *Enterobacteriaceae* bacteraemia involving 1584 patients, mostly adults showed lower mortality than non-Beta-lactam/Beta-Lactam Inhibitor combination antibiotics for definitive [risk ratio (RR) 0.65, 95% CI 0.47–0.91] and empirical (RR 0.50, 95% CI 0.33–0.77) treatment. No statistically significant differences in mortality were found between carbapenems and BL/BLIs administered as definitive (RR 0.52, 95% 0.23–1.13) or empirical (RR 0.91, 95% CI 0.66–1.25) treatment (LOE 1, GOR C).[2] A retrospective case series of 100 neonates infected by extended-spectrum beta-lactamase-producing *Klebsiella* species showed higher mortality in those neonates not started on empirical meropenem or Piperacillin + tazobactam and amikacin (OR – 17.01, 95% CI 2.41–120.23) (LOE IV, GOR C).[3] A RCT reported a prolonged infusion (4 hours) of meropenem (20 mg/kg/dose every 8 hours and 40 mg/kg/dose every 8 hours in meningitis and Pseudomonas infection) in 102 neonates with gram-negative late onset infection is associated with higher rate of clinical improvement, microbiologic eradication, less neonatal mortality (14% versus 31%; p=0.03), shorter duration of respiratory support and less acute kidney injury compared with the conventional strategy (30 minute infusion) [LOE II GOR B].[5] **Pharmacokinetics:** Meropenem is primarily excreted via the kidneys. Meropenem clearance is influenced by serum creatinine and postmenstrual age in neonates.[2] A comparative pharmacokinetic study of short (30 minute) versus long (4 hour) infusion in neonates showed short infusion resulted in a higher mean drug concentration in serum (C(max)) than a prolonged infusion.[6] However, a longer infusion may have greater efficacy.[5] There is a knowledge gap in pharmacokinetic (PK) studies of neonates with renal impairment.[2,3] However, dose adjustment for renal failure may not be appropriate in cases where severe sepsis is probably responsible for acute renal failure [expert opinion]. **Dose:** Multicentre, prospective PK study conducted in USA suggested a dosing strategy of 20 mg/kg every 12 hours in infants < 32 weeks GA and PNA < 14 days; 20 mg/kg every 8 hours in infants < 32 weeks GA and PNA ≥ 14 days and in infants ≥ 32 weeks GA and PNA < 14 days; and 30 mg/kg every 8 hours in infants ≥ 32 weeks GA and PNA ≥ 14 days to achieve therapeutic concentrations in infants with suspected intra-abdominal infections.[4]
